Predicted Weights and Volumes of Northern Red Oak Trees in Western North Carolina

by Alexander Clark III, Douglas R. Phillips, and James G. Schroeder

Conversion factors: English to metric

| Multiply | by | To obtain |
|-----------------------|--------|---------------------------|
| Inches | 2.540 | centimeters |
| Feet | .3048 | meters |
| Pounds | .4536 | kilograms |
| Cubic feet | .02832 | cubic meters |
| Pounds per cubic feet | 16.02 | kilograms per cubic meter |

All English units of measure in this report can be converted to metric units by multiplying by the appropriate conversion factor listed above.

Predicted Weights and Volumes of Northern Red Oak Trees in Western North Carolina¹

by

Alexander Clark III, Wood Scientist Douglas R. Phillips, Mensurationist Forestry Sciences Laboratory Athens, Georgia

and

James G. Schroeder, Wood Scientist Asheville, North Carolina

ABSTRACT.—Total weights and volumes, above stump, were determined for 71 northern red oak (Quercus rubra L.) trees 6 to 24 inches d.b.h. growing in fully stocked oak-hickory stands in western North Carolina. Equations are presented for predicting green and dry weights and green volume of the total tree, above stump, and its components using d.b.h. and total height, d.b.h. and height to a 4-inch top, d.b.h. and saw-log merchantable height, and d.b.h. alone. Tables developed from equations show weight and volume of the total tree and its components by d.b.h. and total height classes. Seventy-five percent of total-tree weight was in stem to a 4-inch top and 25 percent in crown. The average tree had 85 percent of its green weight in wood and 15 percent in bark. Total-tree wood had an average specific gravity of 0.581, an average moisture content of 80 percent, and an average green weight per cubic foot of 65 pounds. The average weight of wood and bark per cubic foot of wood for the total tree was 77 pounds.

Keywords: Quercus rubra L., biomass, component proportions, equations, specific gravity, moisture content, weight per cubic foot.

Increasing demands for wood, escalating costs, and the energy shortage have forced forest industries in the South to consider utilizing all parts of trees. Utilizing the total tree above the stump compared to utilizing only the merchantable stem can increase yields from individual hardwood trees by as much as 65 percent (Clark 1978). Equations for estimating total-tree weight and volume are needed to evaluate and utilize total trees.

This Paper presents green volumes and green and dry weights of above-stump biomass of commercial-size northern red oaks (*Quercus rubra* L.) growing in uneven-aged stands in the mountains of western North Carolina. Equations and yield

tables predict weight and volume of the total tree and its components (wood, bark, saw logs, stem, and crown). Wood and bark specific gravity, moisture content, and green weight per cubic foot are presented for the total tree and its components.

PROCEDURES

Field

A total of 71 northern red oak trees were selected from two fully stocked, uneven-aged oak-hickory stands to determine winter biomass. A stratified random sample of 36 pulpwood-size trees (trees 5.6 to 11.5 inches d.b.h.) was selected from a stand in Haywood County on the French Broad District of the Pisgah National Forest. The dominant and codominant trees in the stand were 10 to 14 inches d.b.h., and the stand had an average site index for northern red oak of 80. Five

¹This study was conducted in cooperation with the Range, Timber, and Wildlife Program Area of Region 8 of the National Forest System. Field personnel were provided by the Pisgah and French Broad Ranger Districts of the Pisgah National Forest.

to seven trees were selected from each 1-inch d.b.h. class from 6 to 11 inches d.b.h. The trees sampled ranged from 41 to 55 years old and averaged 49 years.

A second stratified random sample of 35 dominant and codominant sawtimber-size trees (≥ 11.6 inches d.b.h.) was selected from a mature stand in Buncombe County on the Pisgah District of the Pisgah National Forest. The stand had an average site index of 90. Three to six trees from each 2-inch d.b.h. class were sampled. Form class of the sawtimber trees ranged from 71 to 86 and averaged 79. The trees ranged from 53 to 114 years old and averaged 76 years. Means and ranges in dimensions of sample trees are shown in table 1.

Trees were felled and limbed during the winter, and the main stem of each tree was bucked into merchantable saw logs and pulpwood. Saw logs 8 to 16 feet long were cut from the main stem to an 8-inch d.i.b. top or to a degrading quality indicator such as large knots. Stem d.i.b. at the saw-log top averaged 9.9 inches (table 1). All material between the saw-log merchantable top and the 4-inch d.i.b. top was classed as "pulpwood." All trees had a discernible main stem to a 4-inch top. In pulpwood trees, stem material be-

tween the 4-and 2-inch d.i.b. tops was classed as "topwood." The crown of sawtimber-size trees was cut up and weighed in two categories: (1) branches \geq 4.0 inches d.o.b., and (2) branches < 4.0 inches d.o.b. Pulpwood crowns were divided into branches \geq 2.0 inches and branches < 2.0 inches d.o.b. The tip of the stem (2 inches d.i.b. to top) was included as branch material in the study. All crown and pulpwood material was weighed to the nearest one-quarter pound. Saw logs were weighed individually to the nearest pound.

From each sawtimber tree, disks were removed at the butt, at each saw-log bucking point, at the points where d.i.b. measured 8, 6, and 4 inches, and from branches randomly selected from each branch-size category. In pulpwood-size trees, disks were cut at the butt, at quarter points to a 4-inch top, and at a 2-inch top. Each disk was sealed in a polyethylene bag for subsequent determinations of moisture content, specific gravity, and bark percent.

Laboratory

Specific gravity was computed on a green-volume and ovendry-weight basis. Moisture con-

¹Height to 8-inch d.i.b. or saw-log merchantable top.

tent was computed on an ovendry-weight basis after samples were dried to a constant weight at 103° C. Percentage of bark was determined from disks on a green-weight basis. Moisture content, specific gravity, and percentage of bark in stem, branches, and total tree were calculated by weighting disk values in proportion to the volume of the component they represented. Weighted values for moisture content were used to convert component green weights to ovendry weights.

Green weights per cubic foot of wood and bark were calculated from weighted values for specific gravity and moisture content with the equation:

Green weight per cubic foot

$$= \left[1 + \frac{\text{M.C.}}{100}\right] \times (\text{S.G.}) \times (\text{C}) \tag{1}$$

where:

M.C. = weighted moisture content in percent, S.G. = weighted specific gravity,

= 62.4 pounds (weight of water per cubic foot).

Cubic-foot volume of green wood and bark were computed by dividing component weight by its green weight per cubic foot. Total green cubicfoot volume (wood and bark combined) was computed by adding the green volume of bark to the green volume of wood.

Analysis

Linear regression equations were developed to predict green and dry weights and green volumes of wood and bark in the total tree and its components. Independent variables were: diameter at breast height (D), total height (Th), sawlog merchantable height (Mh), and height to a 4-inch top (H4), both separately and in various combinations.

Grouping the data into D2Th classes and plotting the variance of Y over D2 and D2Th indicated that the variances of predicted weights and volumes increased with increasing D² and D²Th. A logarithmic transformation (to the base 10) was used to obtain a relatively homogeneous variance, which is assumed in regression analysis. Thus, regression equations for tree and component weights and volumes were calculated using the equations:

$$\log Y = b_0 + b_1 \log X + \epsilon \tag{2}$$

$$\log Y = b_0 + b_1 \log X_1 + b_2 \log X_2 + \epsilon$$
(3)

where:

= predicted weight or volume of component

 $X = D^2$, D^2Th , D^2H4 , or D^2Mh ,

 $X_1 = D^2,$

 $X_2 = Th, H4, or Mh$ ϵ = sampling error,

b_i = regression coefficients.

When logarithmic estimates are converted back to original units, they are biased downward because the antilogarithm of an estimated mean gives the geometric rather than the arithmetic mean (Cunia 1964). To account for this bias, a correction factor was computed using a procedure described by Baskerville (1972) and applied to each equation. The equation forms, including the correction factor, are:

$$Y = 10^{b_0 + b_1 \log X + \frac{S_{y \cdot x}^2}{2}}$$
 (4)

and

$$Y = 10^{b_0 + b_1 \log X_1 + b_2 \log X_2 + \frac{S_{y \cdot x}^2}{2}}$$
 (5)

where:

 $S_{y \cdot x}^2 = \text{error mean square from regression}$

Equations (4) and (5) can be simplified to:

$$Y = aX^{b_1} \tag{6}$$

and

$$Y = aX_1^{b_1}X_2^{b_2} (7)$$

where:
$$a = 10^{b_0 + \frac{S_{y \cdot x}^2}{2}}$$

Separate prediction equations were developed for the pulpwood and sawtimber trees. Statistical tests (Snedecor and Cochran 1967) indicated no significant differences in the slopes or intercepts of these equations at the 0.01 probability level for the total tree and stem weights or volumes. Therefore, the pulpwood and sawtimber trees were combined, and one series of equations was developed for trees 6 to 24 inches d.b.h.

SAMPLE TREE CHARACTERISTICS

Total Tree

Green weight of the trees sampled ranged from an average of 457 pounds for 6-inch trees to 12,535 pounds for 24-inch trees. Assuming the trees were composed solely of wood, bark, and water, 44 percent of their green weight was water; 47 percent was wood; and 9 percent was bark. The proportions of total-tree weight in wood and bark did not vary with tree size. The proportion of tree weight in bark ranged from 14 to 17 percent and averaged 15 percent on a green basis. On a dry basis, bark made up an average of 17 percent of total-tree weight.

The proportion of tree weight in crown material (all live branches and stem < 4-inch d.i.b.) ranged from 19 to 29 percent on a green basis but did not vary consistently with tree size. The proportion of tree green weight in crown averaged 25 percent, and the proportion in the stem to a 4-inch top averaged 75 percent.

The green and dry weights of all wood and

bark and the distribution of wood and bark throughout the tree are presented in tables 2 and 3 for pulpwood trees and in tables 4 and 5 for sawtimber trees. On the average, pulpwood trees had 79 percent of their total green wood weight in the stem to a 4-inch d.i.b. top and 21 percent in the crown (topwood and branches). Sawtimber trees on the average had 77 percent of their green wood weight in the stem to a 4-inch top and 23 percent in crown. Sixty-six percent of their green wood weight was in saw-log material and 11 percent in pulpwood. Wood and bark were not distributed evenly throughout the tree; the stem to a 4-inch top of the average sawtimber tree contained 77 percent of all the green wood in the tree but only 61 percent of the bark. Sawtimber tree crowns contained 23 percent of the green wood and 39 percent of the bark.

Stem Components

The proportion of stem weight to a 4-inch top in wood increased and the proportion in bark decreased as stem d.b.h. increased. The proportion of stem weight in wood increased from 85 percent

in 6-inch trees to 88 percent in 24-inch trees, while the proportion in bark decreased from 15 percent in 6-inch trees to 12 percent in 24-inch trees. On the average, 88 percent of the stem green weight was wood and 12 percent was bark.

Crown Components

When the crown was analyzed separately, the proportion of its green weight in wood averaged 77 percent and the proportion in bark averaged 23 percent on a green basis. Comparable figures on a dry basis were 78 and 24 percent, respectively.

On the average, 6 percent of the weight of wood in pulpwood trees was in topwood, 5 percent in branches \geq 2.0 inches d.o.b., and 10 percent was in branches < 2.0 inches d.o.b. (table 2). The average sawtimber tree had 12 percent of its wood in crown material \geq 4.0 inches d.o.b. and 11 percent in branches < 4.0 inches d.o.b. (table 4).

Physical Properties

Wood and bark specific gravity, moisture content, and green weight per cubic foot for the total tree and its components are presented in table 6. Wood specific gravity and moisture content did not vary significantly with tree size. Wood specific gravity averaged 0.581 for the total tree and 0.574 for the stem—slightly higher than the 0.56 reported by the Forest Products Laboratory (1974) for northern red oak stem wood. Pulpwood had the highest wood specific gravity, averaging 0.608, and saw-log wood the lowest. averaging 0.568. Wood moisture content ranged from 69 percent in the branches to 85 percent in saw logs and averaged 80 percent for the total tree. Green weight of wood per cubic foot averaged 65 pounds in the main stem and total tree.

Specific gravity of bark was lowest in branches (0.589) and highest in the pulpwood sec-

²Pulpwood in stem from saw-log top to 4-inch d.i.b. top.

³Main stem to 4-inch d.i.b. top.

Table 6.—Average wood and bark specific gravity, moisture content, and green weight per cubic foot for northern red oak trees and tree components

| | Average and standard deviation | | | | | |
|-------------------------------------|-----------------------------------|--------------|-----------------------------|--|--|--|
| Tree component | Specific Moisture gravity content | | Green weight per cubic foot | | | |
| | | Percent | Pounds | | | |
| | WOOD | | | | | |
| Total tree | 0.581 ± 0.020 | 80 ± 4.9 | 65 ± 1.5 | | | |
| Stem (butt to 4-inch d.i.b. top) | $.574 \pm .021$ | 83 ± 5.4 | 65 ± 1.7 | | | |
| Saw log (butt to 8-inch d.i.b. top) | $.568 \pm .022$ | 85 ± 5.8 | 66 ± 1.5 | | | |
| Pulpwood (8- to 4-inch d.i.b. top) | $.608 \pm .026$ | 72 ± 4.7 | 65 ± 1.9 | | | |
| Branches | $.605 \pm .024$ | 69 ± 4.0 | 64 ± 1.9 | | | |
| | BARK | | | | | |
| Total tree | $0.616 \pm .028$ | 63 ± 5.8 | 62 ± 2.0 | | | |
| Stem (butt to 4-inch d.i.b. top) | $.631 \pm .032$ | 61 ± 6.1 | 63 ± 2.3 | | | |
| Saw log (butt to 8-inch d.i.b. top) | $.634 \pm .038$ | 58 ± 6.0 | 63 ± 2.5 | | | |
| Pulpwood (8- to 4-inch d.i.b. top) | $.658 \pm .038$ | 55 ± 4.8 | 64 ± 2.2 | | | |
| Branches | $.589 \pm .046$ | 66 ± 9.0 | 61 ± 2.6 | | | |

tion of the main stem (0.658). Total-tree bark specific gravity was higher than wood specific gravity and averaged 0.616. Bark moisture content averaged 63 percent for the total tree, lower than the corresponding value for wood. Bark moisture content was the highest in branches (66 percent) and lowest in pulpwood (55 percent). Green bark weight per cubic foot ranged from 61 pounds in branches to 64 pounds in pulpwood and averaged 62 pounds in the total tree.

The weight of wood and bark per unit volume of wood is a useful factor for estimating the volume of wood in a tree or its components when weight of wood and bark is known. The average green weight of wood and bark per cubic foot of wood was 77 pounds for the total tree and 75 pounds for the stem (table 7). Branch green weight of wood and bark per cubic foot of wood averaged 83 pounds.

Green weight per cubic foot of wood and bark combined averaged 65 pounds for the total tree and the stem and 63 pounds for branches (table 7).

PREDICTION EQUATIONS

A series of equations was developed to predict weights and volumes of total trees and their components. Since tree height is measured to different top limits by various organizations, equations were developed using D² alone and in com-

bination with Th, H4, and Mh as independent variables. When Th and H4 were used with D2. the one-variable equation (2) and two-variable equation (3) predicted total-tree and component weights and volumes equally well. The use of height as a separate variable did not improve the coefficient of determination or reduce the standard error. Thus, the single variable equation was used to predict tree weight and volume when using D2, D2Th, and D2H4 as the independent variable. When D² and Mh were used as separate variables in equation (3), the coefficient of determination (R2) increased 15 to 20 percent and the standard error was reduced. Thus, the twovariable equation was used when D2 and Mh were the independent variables.

All independent variable combinations were good predictors of weights and volumes, but equations using D2Th were the best predictors of total-tree weights and volumes. Equations using D2 + Mh were the best estimators of saw-log merchantable stem weight and volume, while equations using D2H4 were the best predictors of stem weight and volume to a 4-inch top. When average tree heights and stem taper are similar to those of our sample trees, the equations using d.b.h. alone will result in good estimates of tree weight and volume. However, when average tree heights by d.b.h. classes are different, the equations that include a height variable should be ap-

Table 7.—Average green weight of wood and bark per cubic foot of wood and average weight of wood and bark per cubic foot of wood and bark for northern red oak trees and tree components

| | Average and standard deviation | | | | |
|------------------------------------|--|---|--|--|--|

| Stem (butt to 4-in. d.i.b. top) | 75 ± 1.9 | 65 ± 1.5 | | | |
| Saw log (butt to 8-in. d.i.b. top) | 75 ± 1.8 | 65 ± 1.5 | | | |
| Pulpwood (8- to 4-in. d.i.b. top) | 78 ± 3.2 | 65 ± 1.6 | | | |
| Branches | 83 ± 3.2 | 63 ± 1.7 | | | |

plied directly or used to develop local weight-volume tables based on d.b.h. alone.

Appendix tables 8 and 9 present equations for predicting all weights and volumes measured for total trees and all their components using D^2Th . Appendix tables 10 and 11 present equations that use D^2 , D^2H4 , and $D^2 + Mh$ to predict the green weights of wood and bark and volume of wood for the most important tree components. The Appendix also describes a method for placing confidence limits about predictions made with the equations.

A complete list of equations based on D², D²H4, and D²Mh for predicting the green and dry weights and volume of wood and bark of all tree components listed in tables 8 and 9 is available from the authors at the Southeastern Forest Experiment Station, Forestry Sciences Laboratory, Athens, Georgia 30602. Also available are uncorrected sums, sums of squares, and their cross products for the independent and dependent variables listed in tables 8 and 9. These data make it possible to statistically compare and combine equations. They also allow for the addition of observations and for computation of error terms.

BIOMASS TABLES

Equations based on D²Th from tables 8 and 9 were used to develop tables of biomass weight and volume. Tables 12–15 show predicted green weights of wood and bark and wood alone in the total tree, the saw-log stem to an 8-inch d.i.b. or saw-log merchantable top, the stem to a 4-inch d.i.b. top, and the crown. Tables 16–19 show pre-

dicted green volumes of wood and bark and wood alone in the total tree and its components. The predicted weight or volume of bark in a tree or component can be estimated by subtracting the value in the table for wood alone from the corresponding value in the table for wood and bark combined.

Similar-size trees may vary in weight and volume because of differences in crown size, stem taper, and weight per cubic foot. Therefore the equations and tables should be applied only to trees growing in natural, fully stocked stands which have stem taper rates and weights per cubic foot similar to the trees sampled.

COMPUTATION OF CONFIDENCE LIMITS

Tables 8, 9, 10, and 11 contain the standard errors of the estimate, the sample mean of x, and the corrected sums of squares for x for each equation in \log_{10} form. These statistics can be used to calculate approximate confidence limits in pounds or cubic feet using a modification of Cox's formula (Land 1972) for estimating confidence limits for lognormal means:

$$Y_{U,L} = 10^{\log Y \pm Z} \sqrt{S^{2}y \cdot x \left[\frac{1}{n} + \frac{(x - \overline{x})^{2}}{\Sigma(x - \overline{x})^{2}}\right] + \frac{S^{1}y \cdot x}{2(n+1)}}$$
(8)

where:

= upper and lower limits for Y, $Y_{U,L}$ = predicted weight or volume of component from equation (6),Z = value from the standard normal table for appropriate confidence level, = standard error of estimate for $S_{v \cdot x}$ prediction equation, = number of observations used n to develop equation, \bar{x} = sample mean of log x — (from table of equations), $\sum (x-\overline{x})^2$ = corrected sums of squares for $\log x$ — (from table of equations), = value of independent variable Х in log_{10} form.

Cox's method of approximation sufficiently estimates actual confidence limits when applied to samples with small variances as occur in the total tree and stem weight and volume of northern red oak data sets. Thus, equation (8) should be used to approximate confidence limits for the single-variable equations presented in this Paper.

¹Blocked-in area indicates range of data.

²Includes 1-foot stump allowance. ³Y = 0.000889 (D²Th)^{0.98263}. ⁴Y = 0.000697 (D²Th)^{0.97993}.

Clark, Alexander, III, Douglas R. Phillips, and James G. Schroeder 1980. Predicted weights and volumes of northern red oak trees in western North

Predicted weights and volumes of northern red oak trees in western North Carolina. USDA For. Serv., Res. Pap. SE-209, 22 p. Southeast. For. Exp. Stn., Asheville, N.C.

Equations are presented for predicting green and dry weights and volume of the total tree. above stump, and its components using d.b.h. and total height, d.b.h. and height to a 4-inch top, d.b.h. and saw-log merchantable height, and d.b.h. alone. Tables developed from equations show weight and volume of the total tree and its components, by d.b.h. and total-height class.

KEYWORDS: *Quercus rubra* L., biomass, component proportions, equations, specific gravity, moisture content, weight per cubic foot.

Clark, Alexander, III, Douglas R. Phillips, and James G. Schroeder

0. Predicted weights and volumes of northern red oak trees in western North Carolina. USDA For. Serv., Res. Pap. SE-209, 22 p. Southeast. For. Exp. Stn.,

Asheville, N.C.

Equations are presented for predicting green and dry weights and volume of the total tree, above stump, and its components using d.b.h. and total height, d.b.h. and height to a 4-inch top, d.b.h. and saw-log merchantable height, and d.b.h. alone. total-height class.

The Forest Service, U.S. Department of Agriculture, is dedicated to the principle of multiple use management of the Nation's forest resources for sustained yields of wood, water, forage, wildlife, and recreation. Through forestry research, cooperation with the States and private forest owners, and management of the National Forests and National Grasslands, it strives—as directed by Congress—to provide increasingly greater service to a growing Nation.

USDA policy does not permit discrimination because of race, color, national origin, sex or religion. Any person who believes he or she has been discriminated against in any USDA-related activity should write immediately to the Secretary of Agriculture, Washington, D.C. 20250.
